

# AVL Trees

1

## AVL Tree Definition

- ◆ An AVL Tree is a balanced **binary search tree** such that for every internal node  $v$  of  $T$ , the **heights of the children of  $v$**  can differ by at most 1 (**Height-Balance Property**)

AVL Trees

2

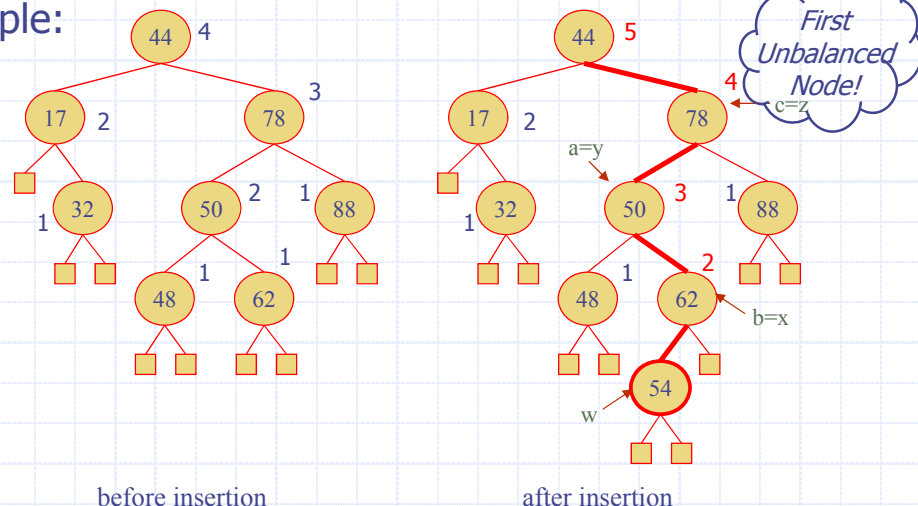

# Height of an AVL Tree (Page 444)

- ◆ **Fact:** The **height** of an AVL tree storing  $n$  keys is  $O(\log n)$ .
- ◆ **Proof:** Let us bound  $n(h)$ : the minimum number of internal nodes of an AVL tree of height  $h$ .
- ◆ We easily see that  $n(1) = 1$  and  $n(2) = 2$
- ◆ For  $n > 2$ , an AVL tree of height  $h$  contains the root node, one AVL subtree of height  $h-1$  and another of height  $h-2$ .
- ◆ That is,  $n(h) = 1 + n(h-1) + n(h-2)$
- ◆ Knowing  $n(h-1) > n(h-2)$ , we get  $n(h) > 2n(h-2)$ . So  
 $n(h) > 2n(h-2)$ ,  $n(h) > 4n(h-4)$ ,  $n(h) > 8n(h-6)$ , ... (by induction),  
 $n(h) > 2^i n(h-2i)$
- ◆ Solving the base case we get:  $n(h) > 2^{h/2-1}$
- ◆ Taking logarithms:  $h < 2 \log n(h) + 2$
- ◆ Thus the height of an AVL tree is  $O(\log n)$

## Insertion

- ◆ Insertion is as in a binary search tree
- ◆ Always done by expanding an external node.
- ◆ Example:

before insertion

after insertion

# Violation of HBP

Assume that "z" is the first unbalanced node encountered after insertion

◆ Case I

◆ Case II

The height of "z" will become  $n+3$  after insertion!

AVL Trees

5

Case I. Node  $w$  is added to  $P$

Can't be both  $n+1$ . Why?

AVL Trees

6

## Case II. Node w is added to Q

Can't be both  $n+1$ . Why?

AVL Trees

7

## Case I-1: $R : n+1, S : n$ ( $w$ is added to $R$ )

AVL Trees

8

Case I-2: R : n, S : n+1  
(w is added to S)

AVL Trees

9

Case II-1: R : n+1, S : n  
(w is added to R)

AVL Trees

10

Case II-2: R :  $n$ , S :  $n+1$   
(w is added to S)

AVL Trees

11

## Trinode Restructuring

- ◆ Let  $z$  be the first node we encounter in going up from  $w$  towards the root
- ◆ Let  $y$  be the child of  $z$  with higher height ( $y$  must be an ancestor of  $w$ )
- ◆ Let  $x$  be the child of  $y$  with higher height
  - There cannot be a tie and node  $x$  must be an ancestor of  $w$  including itself

AVL Trees

12

# Trinode Restructuring (Cont'd)

- ◆ Let  $a, b, c$  be a left-to-right (inorder) listing of the nodes  $x, y, z$ .
- ◆ Let  $T_0, T_1, T_2, T_3$  be a left-to-right (inorder) listing of the four subtrees of  $x, y$ , and  $z$
- ◆ Make node  $b$  as the new root.
- ◆ Let  $a$  be the left child of  $b$  and let  $T_0$  and  $T_1$  be the left and right child of  $a$ , respectively.
- ◆ Let  $c$  be the right child of  $b$  and let  $T_2$  and  $T_3$  be the left and right child of  $c$ , respectively.

Case I-1:  
Restructure → Single Rotation Right

Case I-2:  
Restructure → Double Rotation Left-Right

AVL Trees

15

Case II-1:  
Restructure → Double Rotation Right-Left

AVL Trees

16

Case II-2:  
Restructure → Single Rotation Left

AVL Trees

17

## Insertion Example (Cont'd)

AVL Trees

18

# Removal

- ◆ Removal begins as in a binary search tree. However, Its parent, w, may cause an imbalance.
- ◆ Example:

AVL Trees

19

# Rebalancing after a Removal

- ◆ Let **z** be the **first unbalanced** node encountered while travelling up the tree from w. Also, let y be the child of z with the larger height, and let x be the child of y with the larger height
- ◆ We perform **restructure(x)** to restore balance at z
- ◆ As this restructuring may upset the balance of another node higher in the tree, we must continue checking for balance until the root of T is reached

20

# AVL Tree Performance

- ◆ a single restructure takes  $O(1)$  time
  - using a linked-structure binary tree
- ◆ **get** takes  $O(\log n)$  time
  - height of tree is  $O(\log n)$ , no restructures needed
- ◆ **put** takes  $O(\log n)$  time
  - initial find is  $O(\log n)$
  - Restructuring up the tree, maintaining heights is  $O(\log n)$
- ◆ **remove** takes  $O(\log n)$  time
  - initial find is  $O(\log n)$
  - Restructuring up the tree, maintaining heights is  $O(\log n)$
